# Solutions to Sheet 10

### Exercise 1

Let  $p \geq 2$  be a prime number and let  $K = \mathbb{Q}(\zeta)$  be the p-th cyclotomic field, where  $\zeta = e^{2\pi i/p} \in \mathbb{C}$ . The minimal polynomial of  $\zeta$  over  $\mathbb{Q}$  is  $\Phi_n(X) = X^{p-1} + \cdots + X + 1$ . Let  $l_1, \ldots, l_n$  be prime numbers such that  $l_i \equiv 1 \mod p$  for all i and set  $L = l_1 \cdots l_n$ .

- 1. Show that there xists  $x \in \mathbb{Z}$  with  $\Phi(xLp) > 1$ .
- 2. Denote by l a prime number that divides  $\Phi_p(xLp)$ . Show that  $l \notin \{l_1, \ldots, l_n\}$  and  $l \neq p$ .
- 3. Let  $\mathfrak{l}$  be a prime ideal of  $\mathcal{O}_K$  containing l. Show that  $f(\mathfrak{l}|l\mathbb{Z})=1$  and deduce that  $l\equiv 1 \mod p$ .
- 4. Deduce that there exists infinitely many prime numbers l such that  $l \equiv 1 \mod p$ .

#### Solution.

- 1. This is simple analysis. The term  $X^{p-1}$  dominates and gets arbitrarily large.
- 2. One quickly finds  $\Phi_p(xLp) \equiv 1 \mod l_i$  and mod p.
- 3. Again, this is an application of Dedekind-Kummer. Again, we can apply Dedekind-Kummer with respect to  $\zeta$ , as  $\mathcal{O}_K = \mathbb{Z}[\zeta]$ , i.e.,  $[\mathcal{O}_K : \mathbb{Z}[\zeta]] = 1$ . Now  $\mathfrak{l}$  corresponds to some factor of the decomposition of  $\Phi_n(X)$  mod l. As  $\Phi_n(xLp) \equiv 0 \mod l$  (i.e., thre is a root), there is at least one linear term in the decomposition of  $\Phi_n(X)$ . Let this term correspond to some prime ideal  $\mathfrak{l}' \mid l\mathcal{O}_K$ , which now has residue degree  $f(\mathfrak{l}'|l) = 1$  (again, by 3.11). But  $\mathbb{Q}(\zeta)/\mathbb{Q}$  is Galois, so the residue degrees of primes over l are all the same. Hence  $f(\mathfrak{l}|l) = 1$ . Proposition 40 now yields that  $l \equiv 1 \mod p$ .
- 4. Given any finite list  $l_1, \ldots, l_n$  of primes leaving residue 1 mod p, we can take their product L and find some integer x > 1 such that  $\Phi_n(xLp) > 1$  by part 1. Now any prime l dividing  $\Phi_n(xLp)$  is not among the  $l_i$  and  $\neq p$  by part 2, and part 3 shows that  $l \equiv 1 \mod p$ . So no finite list of primes 1 mod p can contain all such primes.

## Exercise 2

Let m < 0 be a squarefree integer and set  $K = \mathbb{Q}(\sqrt{m})$ .

1. Show that  $N_{K/\mathbb{Q}}(x) > \left| \Delta_{K/\mathbb{Q}} \right| / 4$  for all  $x \in \mathcal{O}_K \setminus \mathbb{Z}$ .

### Solution.

1. Remember the formula for the discriminant of quadratic number fields:

$$\Delta_{\mathbb{Q}(\sqrt{m})/\mathbb{Q}} = \begin{cases} 4m, & \text{if } m \equiv 2, 3 \pmod{4} \\ m, & \text{if } m \equiv 1 \pmod{4}. \end{cases}$$

If  $m \equiv 1 \mod 4$ , this has been basically solved by sheet 6, exercise 2.3: There we found that for all  $x \in \mathcal{O}_{\mathbb{Q}(\sqrt{m})}$  we have

$$N_{K/\mathbb{Q}}(x) \ge \left| \frac{m-1}{4} \right| > \left| \frac{m}{4} \right| = \left| \frac{\Delta_{K/\mathbb{Q}}}{4} \right|.$$

The case  $m \equiv 2, 3 \mod 4$  is handled similarly. We have  $\mathcal{O}_K = \mathbb{Z}[\sqrt{m}]$ , and  $N_{K/\mathbb{Q}}(a + b\sqrt{m}) = a^2 + mb^2 \geq m = |\Delta_K|/4$ .

# Exercise 3

- 1. Show that  $Cl(\mathbb{Q}(\sqrt{-2023})) = \{1\}.$
- 2. Show that  $Cl(\mathbb{Q}(\sqrt{-67})) = \{1\}.$

**Solution.** The Idea for both calculations is to follow the proof of lemma 4.4 in the lecture notes. Let  $K = \mathbb{Q}(\sqrt{m})$  with some squarefree integer m < 0 identified as a subfield of  $\mathbb{C}$ , and let  $I \subset \mathcal{O}_K$  be any ideal. We can follow the proof of lemma 4.4 verbatim until just before equation (4.1) to obtain a *reduced*  $\mathbb{Z}$ -basis of  $(a_1, a_2)$  of I. That is, we find elements  $a_1, a_2 \in \mathcal{O}_K$  with  $I = a_1\mathbb{Z} + a_2\mathbb{Z}$ , such that

$$\left|\frac{a_2}{a_1}\right| \geq 1, \quad \operatorname{Re}\left(\frac{a_2}{a_1}\right) \leq 1/2 \quad \text{ and } \quad \operatorname{Im}\left(\frac{a_2}{a_1}\right) \geq 0.$$

just as in the notes we set  $\tau = \frac{a_2}{a_1}$  and find that these conditions relate to  $|\tau| \ge 1$ ,  $|\text{Re }\tau| \le 1/2$  and  $\text{Im}(\tau) \ge 0$ . In particular, we find  $\text{Im }\tau \ge \sqrt{3}/2$ . Lemma 1.44 reads  $\Delta_K(I) = \text{N}(I)^2 \Delta_K = 4bm$ , where b = 1 if  $m \equiv 2, 3 \mod 4$  and b = 4 otherwise. Equation (4.1) also goes through, we find  $\Delta_K(I) = -4|a_1|^4 \text{Im}(\tau)^2$ . Combining these equations, we arrive at

$$2 N(I) \sqrt{\frac{-bm}{3}} \ge |a_1|^2 = N_{K/\mathbb{Q}}(a_1).$$

As  $a_1 \in I$  we find  $I \mid a_1 \mathcal{O}_K$ , so there is some ideal J with  $IJ = a_1 \mathcal{O}_K$  (i.e., [J] is the inverse of [I] in Cl(K)). Now

$$\mathrm{N}(I)\,\mathrm{N}(J) = \mathrm{N}(IJ) = \mathrm{N}(a_1\mathcal{O}_K) = \mathrm{N}_{K/\mathbb{Q}}(a_1) = \left|a_1\right|^2 \leq \mathrm{N}(I)\sqrt{\frac{-bm}{3}},$$

implying that

$$N(J) \le \sqrt{\frac{-bm}{3}}.$$

The hope is now that this is not too large and leaves us with a number of cases that we can handle. So let's see.

- 1. Note that  $2023 = 17^2 \cdot 7$ , so that really  $K = \mathbb{Q}(\sqrt{-7})$ . As -7 is  $1 \mod 4$ , we have b = 1, and we find  $N(J) \leq \sqrt{\frac{7}{3}} < 2$ . There are no prime ideals with norm that low (they cannot lie over a integer prime) so the only possibility is  $J = \mathcal{O}_K$ . But now  $[I] = [J] = \mathrm{id}_{\mathrm{Cl}(K)}$ , and  $\mathrm{Cl}(K) = \{1\}$ .
- 2. Again, -67 is 1 mod 4, but it is already squarefree and relatively large, so we'll have to make use of Dedekind kummer. But first of all, note that again b = 1, so we find

$$N(J) \le \sqrt{\frac{67}{3}} < \sqrt{23} < 5.$$

Now let's inspect the primes above 2 and 3. The ring  $\mathcal{O}_K$  is generated as  $\mathbb{Z}$ -module by  $\frac{1+\sqrt{-67}}{2}$ , which has minimal polynomial  $T^2+T+17$  (I think). Mod 2 we have  $T^2+T+17\equiv T^2+T+1$ , which is irreducible and mod 3 we have  $T^2+T+17\equiv T^2+T+2$ , which is irreducible. So we find by Dedekind-Kummer that both 2 and 3 are inert in  $\mathcal{O}_K$ , hence the only ideal with norm  $\leq 4$  is  $J=2\mathcal{O}_K$ , which is principal. In particular, we find that I has to be principal, hence  $\mathrm{Cl}(K)=\{1\}$ .
